Multiprogramming: Protection – Relocation. → purpose { Better utilization of equipment

1) progs are written separately

2) invironment is "less reliable,"

because 1. other progs. may not be completely debugged
2. machine may make error.

1. indexed refs to mem.
2. lim or count may be computed } cannot check in assembly

Relocation: Pack progs into mem. to avoid idle mem. locs.
during xecution?

we cannot relocate as it stands now
— addresses may be in Temp. storage, acc., etc. { lower 64 addresses are no-man's land

check points in p.p. = where prog can be relocated.

Overlay — bringing in new instrs over old
i.e. put more high used parts of prog. in cores
less used portions in aux. mem.
"community usage" is higher although individual progs are less eff.
